Barcelona Graduate School of Economics

June 29, 2017

# Outline

- State Space Models
- Filtering
  - ▶ Kalman Filter
  - ▶ Sequential Importance Resampling (SIR)
  - ▶ Continuous Sequential Importance Resampling (CSIR)
  - ▶ Importance Sampling Particle Filter
- Evaluation
- Illustration
  - ▶ Trivariate Local Level Model
  - ▶ Hierarchical Dynamic Poisson Model

# State Space Models

# Local Level Model

## Formulation

observation:  $y_t = x_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)$

state:  $x_{t+1} = x_t + \eta_t, \quad \eta_t \sim N(0, \sigma_\eta^2)$

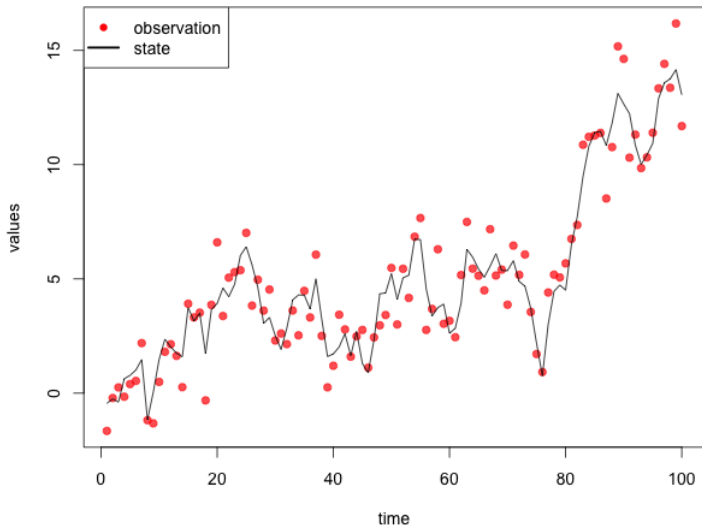

$$\boldsymbol{\theta} = [\sigma_\eta^2, \sigma_\epsilon^2]^T$$

transition density:  $x_{t+1} | x_t, \boldsymbol{\theta} \sim N(x_t, \sigma_\epsilon^2)$

measurement density:  $y_t | x_t, \boldsymbol{\theta} \sim N(x_t, \sigma_\eta^2)$

# Local Level Realization

$$\sigma_{\eta}^2 = 1.4, \sigma_{\epsilon}^2 = 1.0$$

# Filtering

# Filtering

Let  $\mathcal{I}_t = \{y_1, y_2, \dots, y_t\}$ . The objective of filtering is to update our knowledge of the system  $p(x_{0:t}|\mathcal{I}_t, \theta)$  each time a new observation  $y_t$  is brought in.  $p(x_{0:t}|\mathcal{I}_t, \theta)$  can be decomposed in recursive form:

$$p(x_{0:t}|\mathcal{I}_t, \theta) = \left[ \frac{p(y_t|x_t, \theta)p(x_t|x_{t-1}, \theta)}{p(y_t|\mathcal{I}_{t-1}, \theta)} \right] p(x_{0:(t-1)}|\mathcal{I}_{t-1}, \theta)$$

where

- $p(y_t|x_t, \theta)$  is the measurement density
- $p(x_t|x_{t-1}, \theta)$  is the transition density

**Particle filtering:** recursively simulate the transition density and evaluate the measurement density

# Kalman filter

For linear Gaussian state space models,  $p(x_{0:t}|\mathcal{I}_t, \theta)$  is analytically tractable. The **Kalman filter** infers latent states analytically by recursively updating:

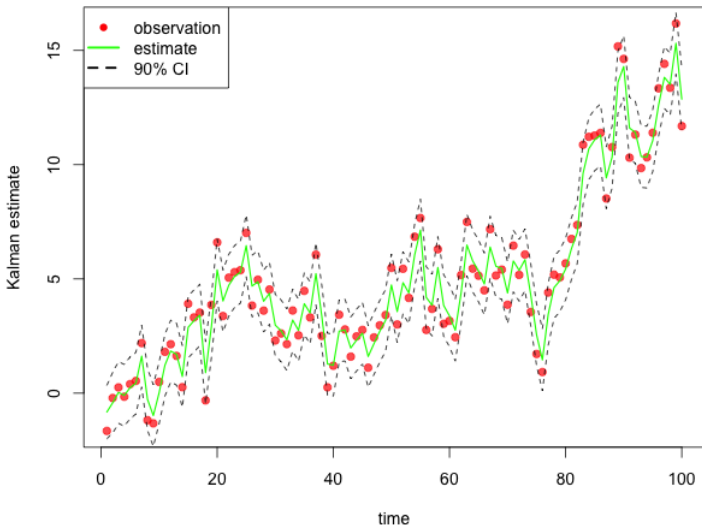

- 1 the prediction density  $x_t|\mathcal{I}_{t-1}, \theta \sim N(\mu_{t|t-1}, \Sigma_{t|t-1})$
- 2 the filtering density  $x_t|\mathcal{I}_t, \theta \sim N(\mu_{t|t}, \Sigma_{t|t})$

Latent state estimates statistically minimize the error and hence are *optimal*.

# Kalman filter

## Latent State Inference

# Sequential Importance Resampling (SIR)

Recursively computes  $P$  prediction and filtering particles:

- 1 **Prediction step:** draw prediction particles from transition density:

$$x_{t|t-1}^i \sim p(x_t | x_{t-1}^i, \theta) \quad \text{for } i = 1, \dots, P$$

- 2 **Filtering step:** draw filtering particles via multinomial sampling:

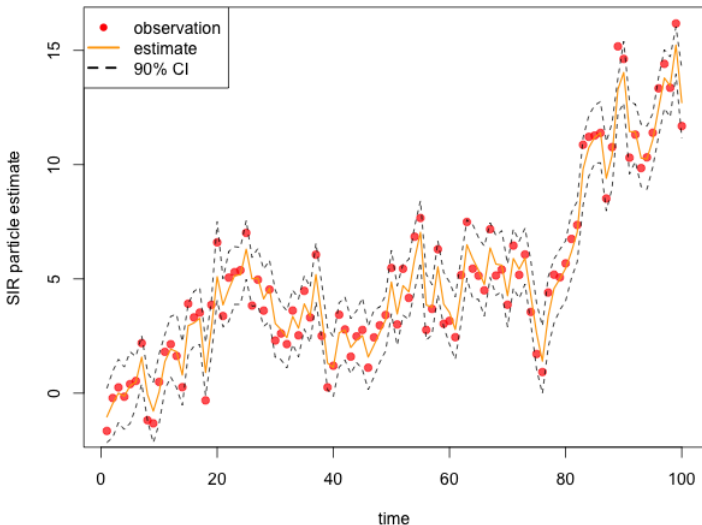

$$x_{t|t}^j \sim MN(w_t^1, \dots, w_t^P) \quad \text{for } j = 1, \dots, P$$

where importance weights are (normalized) evaluations of the measurement density

$$w_t^i = \frac{p(y_t | x_{t|t-1}^i, \theta)}{\sum_{j=1}^P p(y_t | x_{t|t-1}^j, \theta)} \quad \text{for } i = 1, \dots, P$$

# Sequential Importance Resampling (SIR)

## Latent State Inference

# Sequential Importance Resampling (SIR)

## Parameter Inference

Maximum likelihood estimation on the approximated log-likelihood of the observations, given all previous observations:

$$\begin{aligned}\log \hat{\mathcal{L}}(\mathcal{I}_T, \boldsymbol{\theta}) &= \log \prod_{t=1}^T \hat{p}(y_t | \mathcal{I}_{t-1}, \boldsymbol{\theta}) \\ &= \sum_{t=1}^T \log \hat{p}(y_t | \mathcal{I}_{t-1}, \boldsymbol{\theta}) \\ &= \sum_{t=1}^T \log \frac{1}{P} \sum_{i=1}^P p(y_t | x_t^i |_{t-1}, \boldsymbol{\theta})\end{aligned}$$

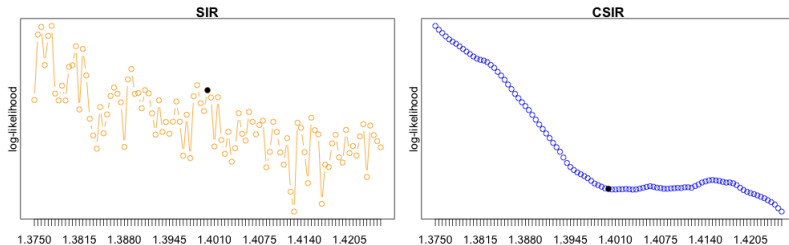

# Continuous Sequential Importance Resampling (CSIR)

**Problem:** Log-likelihood estimator of SIR method w.r.t.  $\theta$  is not smooth. Poor parameter inference results.

**Solution:** Smooth it! Sort prediction particles in ascending order, form (discrete) CDF using associated weights, interpolate CDF, and finally draw filtering particles from this inverted, smoothed CDF.

# Continuous Sequential Importance Resampling (CSIR)

Comparison of log-likelihoods w.r.t.  $\theta$

**Caveat:** CSIR method only works for univariate state space models.

# Importance Sampling Particle Filter

**Key idea:** Use an auxiliary, misspecified particle filter with parameter vector  $\tilde{\theta}$  (independent of  $\theta$ ) to compute the log-likelihood with respect to  $\theta$  via recursive importance sampling.

$$\begin{aligned} p(y_t | \mathcal{I}_{t-1}, \theta) &= \int p(y_t | \tilde{x}_t, \theta) p(\tilde{x}_t | \mathcal{I}_{t-1}, \theta) d\tilde{x}_t \\ &= \int p(y_t | \tilde{x}_t, \theta) \left[ \frac{p(\tilde{x}_t | \mathcal{I}_{t-1}, \theta)}{p(\tilde{x}_t | \mathcal{I}_{t-1}, \tilde{\theta})} \right] p(\tilde{x}_t | \mathcal{I}_{t-1}, \tilde{\theta}) d\tilde{x}_t \\ \hat{p}(y_t | \mathcal{I}_{t-1}, \theta) &\approx \frac{1}{P} \sum_{i=1}^P p(y_t | \tilde{x}_{t|t-1}^i, \theta) \left[ \frac{p(\tilde{x}_{t|t-1}^i | \mathcal{I}_{t-1}, \theta)}{p(\tilde{x}_{t|t-1}^i | \mathcal{I}_{t-1}, \tilde{\theta})} \right] \\ &= \frac{1}{P} \sum_{i=1}^P p(y_t | \tilde{x}_{t|t-1}^i, \theta) is_{t|t-1}^i \end{aligned}$$

# Importance Sampling Particle Filter

## Importance Weights

Recursively computes  $P$  prediction and filtering importance weights:

- 1 **Prediction importance weight:** compares transition densities

$$is_{t|t-1}^i = \left[ \frac{p(\tilde{x}_{t|t-1}^i | \tilde{x}_{t-1|t-1}^i, \theta)}{p(\tilde{x}_{t|t-1}^i | \tilde{x}_{t-1|t-1}^i, \tilde{\theta})} \right] is_{t-1|t-1}^i$$

- 2 **Filtering importance weight:** compares measurement densities and likelihood

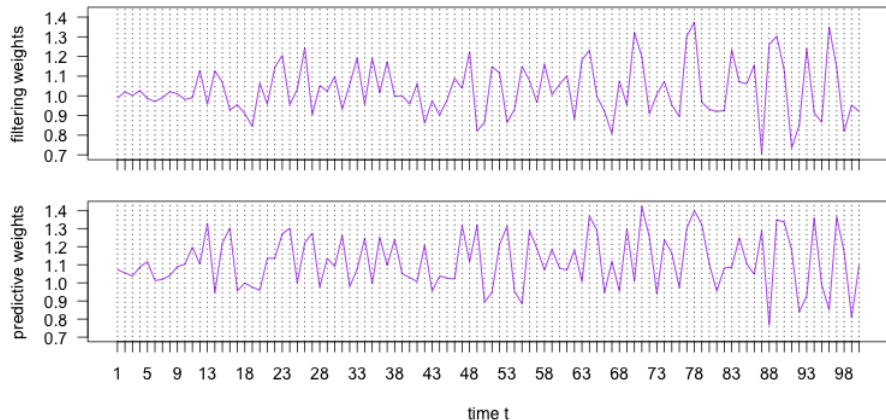

$$is_{t|t}^i = \left[ \frac{p(y_t | \tilde{x}_{t|t}^i, \theta)}{p(y_t | \tilde{x}_{t|t}^i, \tilde{\theta})} \right] \left[ \frac{p(y_t | \mathcal{I}_{t-1}, \tilde{\theta})}{p(y_t | \mathcal{I}_{t-1}, \theta)} \right] is_{t|t-1}^j$$

where  $j$  is such that  $\tilde{x}_{t|t}^i = \tilde{x}_{t|t-1}^j$

# Importance Sampling Particle Filter

## Importance Weights

# Importance Sampling Particle Filter

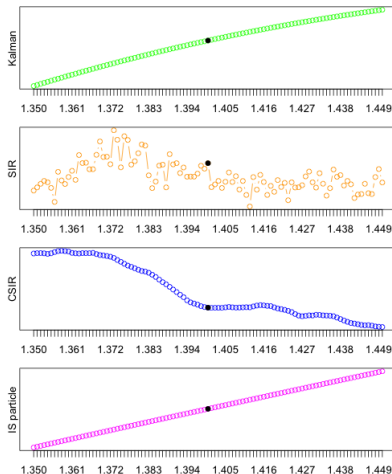

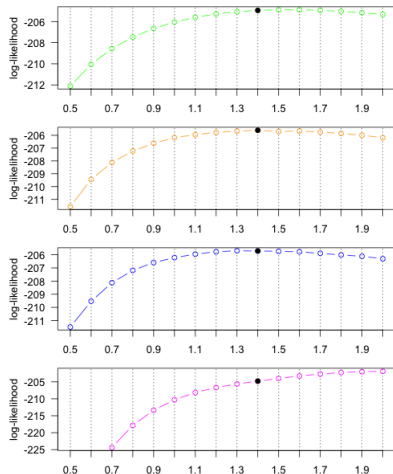

## Parameter Inference

The estimated log-likelihood of  $\theta$  weighs each auxiliary particle  $\tilde{x}_{t|t-1}^i$  with predictive importance weight  $is_{t|t-1}^i$ :

$$\begin{aligned}\log \hat{\mathcal{L}}(\mathcal{I}_T, \theta) &= \log \prod_{t=1}^T \hat{p}(y_t | \mathcal{I}_{t-1}, \theta) \\ &= \sum_{t=1}^T \log \hat{p}(y_t | \mathcal{I}_{t-1}, \theta) \\ &= \sum_{t=1}^T \log \frac{1}{P} \sum_{i=1}^P p(y_t | \tilde{x}_{t|t-1}^i, \theta) is_{t|t-1}^i\end{aligned}$$
